CATALOGUE OF BRITISH EARTHQUAKES RECORDED BY THE BGS
SEISMOGRAPH NETWORK 1979, 1980 AND 1981

1. Introduction

Earthquakes detected and located by BGS in the years 1979, 1980 and 1981 are listed and mapped in the catalogue. The land areas of Great Britain and Northern Ireland and their coastal waters, including the North Sea, are covered within the limits of the detection capabilities of the seismograph network. The expansion of the network with time and its associated effects on detection threshold and uncertainties in location accuracy are discussed and illustrated.

This catalogue continues on from the LOWNET (1967-1978) catalogue of Burton & Neilson (1980).

2. Catalogue Format

2.1 Tables

Hypocentral parameters, for each earthquake, are tabulated under the headings:

Date	- day, month, year.
Origin Time	- hours, minutes, seconds.
Latitude	- positive North.
Longitude	- positive East.
Grid Reference	- in km east and north of National Grid origin, near the Scilly Isles.
Depth	- Hypocentral depth in km, blank indicates depth unknown.
Magnitude	- Richter local (ML) or body-wave (MB) magnitude.
Place	- A geographical indication of the epicentral region, usually the nearest town. 'C' denotes

Midlothian or Fife coalfield.

Int (Io) - Maximum felt intensity on the Modified Mercalli scale, when known. 3+ indicates that the earthquake was reported as felt.

Felt Area - The area in square km enclosed by the MM3 isoseismal.

The earthquakes have been arranged into three tables:

TABLE 1 is a chronological listing of all earthquakes for which a reliable epicentral location could be obtained.

TABLE 2 is a listing of the events in Table 1 arranged in order of decreasing latitude to facilitate identification of the earthquakes in selected regions.

TABLE 3 is a chronological listing of events which, although detected by the seismograph network, had arrival patterns too weak to permit the computation of reliable locations. An indication of the estimated epicentre is given but errors could be very large. These events are not included in Tables 1 or 2.

2.2 Maps

Data from Table 1 is also presented in the maps for the regions described below for the years 1979, 1980 and 1981:

Fig 2 United Kingdom.

Fig 3 North Sea.

Fig 4 Scotland, including Kintail and Ochil Hills series and Midlothian coalfield.

Fig 5 Northern England including Carlisle and N Staffordshire

Fig 6 Wales and SW England, including Newport and Constantine events.

Fig 7 Seismicity map for UK showing all events of magnitude 2.5 ML and above.

3. The BGS Seismograph Network

3.1 Instrumentation

A typical seismic network consists of up to seven 'outstation' vertical seismometers radio-linked over distances of up to 100 km to a central site where the data, along with that from a local 3-component set of two horizontal and one vertical seismometers, are recorded on magnetic tape by a Geostore recorder. Tapes are dispatched, usually once per week, to Edinburgh for analysis.

A more detailed description of the system is given by Browitt (1979) and the response of the instruments is described by Turbitt and Stewart (1982).

At some locations, on-line paper chart recorders display 3-channels to permit rapid investigation of reported felt tremors.

3.2 Geographical Coverage of the Network

In 1969, the then Institute of Geological Sciences (IGS, now BGS), established LOWNET, a network of seismographs across the Lowland Valley of Scotland (Crampin, 1970). By 1978 further stations had been installed near Kyle, Leicester, Leeds, Hereford and Stoke and during the years 1979 to 1981 these networks were supplemented by instruments in Shetland, Moray Firth, Wales, East Anglia, Devon, Cornwall and the North Sea (Beryl). In the same period the Institute of Advanced Studies in Dublin deployed similar instruments in Ireland. A temporary network was installed near Longtown in Cumbria and operated from 29 December 1979 to 23 March 1981 to study the aftershock sequence of the "Carlisle" earthquake.

This has enabled small earthquakes in areas remote from

Edinburgh to be recorded, providing a more complete picture of short-term British seismicity. Figure 1 shows the expansion of the network each year.

Geographical coordinates of the sites are listed in Table 4.

3.3 Detection Threshold

To obtain an estimate of the detection capabilities of the network an earthquake was considered detected when its signal exceeded twice the background noise level on three or more seismographs. Background noise, generated by atmospheric conditions, waves, streams, traffic, cattle etc., varies in amplitude at British seismograph sites from about 0.5 to 15 nanometres, at the typical signal frequency of 10Hz.

At a given range a threshold magnitude was determined, below which an earthquake would not be detected. These threshold magnitudes are plotted as contours on Figure 1, illustrating the increased detection capabilities with the expansion of the network.

The detection contours plotted in Figure 1 hold true only if all stations are continuously monitored and this is not always the case. Small events in unmonitored areas may then go undetected unless felt and reported to BGS by local inhabitants. The detection capabilities by this process are strongly dependent on population density with the consequence that areas such as the Scottish Highlands have a high threshold magnitude at times when local networks are not monitored.

4. Hypocentre Parameters and their Errors

4.1 Epicentre Location

By accurately timing the signal onsets at a minimum of three

stations a location can be found for an earthquake which satisfies the observed pattern of arrivals. Almost all instrumental locations in the catalogue were obtained using the computer program HYP071 (Lee and Lahr, 1975) which iteratively adjusts a trial epicentre (latitude, longitude, depth and origin time) until the observed and computed arrival times coincide closely.

The accuracy of location is dependent on distances from the closest stations, the distribution of the stations around the epicentre and the accuracy with which the seismic wave velocity through the earth can be modelled.

The general velocity model used is given in Table 5 and was derived from a series of refraction profiles traversing Britain, LISPB (Bamford et al., 1976, Bamford et al., 1978, Assumpcao & Bamford, 1978). However, for some localised areas of activity, different models have been employed and these are explained in detail in BGS reports on the particular series.

Epicentral errors from the uncertainties discussed above range from 1 km for the Constantine series (Feb 1981) within the Cornwall network to 5km for the Carlisle mainshock (Dec 1979) where LOWNET was the nearest network some 80 km away. For North Sea events where the nearest stations can be hundreds of kilometres away and poorly distributed in azimuth, errors may be 40 km or more.

4.2 Depth Determination

The accurate determination of earthquake depth presents a more difficult problem, mainly because wave-front arrival patterns at the seismographs can still be satisfied for a large range of depths merely by adjusting the origin time to suit. Constraints on the depth can usually only be imposed when a station is very near the epicentre and even then the accuracy depends on the velocity model.

The best depth determinations have been obtained when a series occurred almost beneath a network as with Constantine and the Carlisle aftershocks where the error is about 2 km. Tremors in the Midlothian coalfield usually have small depth errors due to the proximity of LOWNET stations and can be seen to lie in the first one or two kilometres near the coal workings.

For events at larger distances depth errors may be up to tens of kilometres.

4.3 Seismicity Distribution

Owing to variability in the earthquake detection threshold, which is governed by the ambient noise conditions and the geometry of the observing network (see 3.3 above) the catalogue is biased towards certain localities. In order to present a consistent picture of UK seismic activity for the period, earthquakes with magnitude 2.5 ML or greater have been plotted in Figure 7. The data set is considered to be complete for these magnitudes in all localities.

4.4 Magnitude

Almost all earthquakes in the catalogue have been assigned a local magnitude (ML) as defined by Richter (1935). This has been measured by calculating the equivalent centre to peak displacement on a Wood-Anderson seismometer and applying a distance correction as determined by Richter for California. The scale is logarithmic so that an increase of one point corresponds to a tenfold increase in ground motion or about thirty fold in source energy.

Ideally the measurements are made on two horizontal instruments and averaged but, if this was not possible, the mean of the magnitudes from a number of verticals has been used.

Ground motion at a seismograph varies with site conditions and direction from the earthquake, and for this reason, it is important to take the mean from a good distribution of stations. The resulting error on magnitudes quoted in the catalogue will normally be less than 0.4 ML.

For distances greater than 600 km, where Richter's distance correction does not apply, a body-wave magnitude (MB) is quoted. This has been calculated as MB* according to the formula described by Jacob and Willmore (1972) and is not directly equivalent to ML.

4.5 Intensity

Intensity is a measure of the effect of the shaking on people, structures and objects at a locality. It decreases with distance from a maximum value (I_0) usually found close to the epicentre. The maximum felt intensity is quoted, where known, using the Modified Mercalli scale, 1956 version (Table 6; Richter, 1958) or the equivalent MSK scale (Medvedev et al, 1964).

5. Catalogue Content and Completeness

5.1 The Geographical Area

The catalogue covers all of the UK land mass and its coastal waters including the North Sea. Strict geographical boundaries have not been defined but events have not been included if they would normally appear in other catalogues, e.g. European events. The Norwegian Sea and the Norwegian sector of the North Sea are exceptions to this because of the special economic interest in the oil-producing areas.

5.2 Events Included

All events believed to be due to true tectonic origins have

been included. That is, events caused by natural stresses within the earth.

Coalfield events are also included. These are small events occurring near the coal workings and are caused by the redistribution of stress as the coal is extracted.

The apparently high seismic activity near Edinburgh and Stoke-on-Trent is due to coal mining and similar concentrations might be observed in other coalfields if they were as closely monitored.

5.3 Events excluded

Events that are known, or suspected to be of explosive origin are excluded from the catalogue. Explosions due to quarrying, mining, weapon testing or disposal, naval exercises, geophysical prospecting and civil engineering are all excluded where possible. Unfortunately, identification by record character, location and time of occurrence is not always positive and some man-made events may have been included in the catalogue or, more rarely, a small natural event may have been excluded.

Acoustic disturbances, such as sonic booms from supersonic air-craft are also excluded although they are often reported as earthquakes. These are more readily identified by their relatively slow travel time across an array.

5.4 Completeness

It can be seen from the contours of Figure 1 that in 1979, the whole of the UK was covered by the seismograph network for events of magnitude 2.0 ML (2.8 on a noisy day) and above except for the tip of Cornwall and the Shetland Islands. Normally, however, an earthquake of this size would be felt, if

not detected, in these areas so it can be assumed that the catalogue is probably complete for all earthquakes of magnitude 2.5 and above for 1979.

With the addition of the Welsh and further Shetland stations the catalogue for 1980 is complete for everything above magnitude 2.4 and for 1981, with the addition of the SW England and Jersey stations, all events above 2.0 should be included except, perhaps, for a very small part of SE England on a noisy day.

ACKNOWLEDGEMENTS

Interchange of data with the Dublin Institute of Advanced Studies, the University of Bergen and NORSAR made the location of many of the events in this catalogue possible.

We are indebted to Mobil North Sea Ltd, the Camborne School of Mines, the Universities of East Anglia, Leeds, Leicester and Keele and many other individuals who assisted with station operation.

The work was funded in part by the Department of Energy and the Department of the Environment and was supported by the Natural Environment Research Council. It is published with the approval of the Director of the British Geological Survey (NERC).

YEL	(YELL)	60.5509	-1.0830	450.29 /1185.55	200M	1979-

Table 5 : Typical depth/velocity model for Britain

Depth to top of layer (Kms)	P-wave velocity (Kms/sec)
0.0	4.0
2.52	5.9
7.55	6.45
18.87	7.0
34.15	8.0

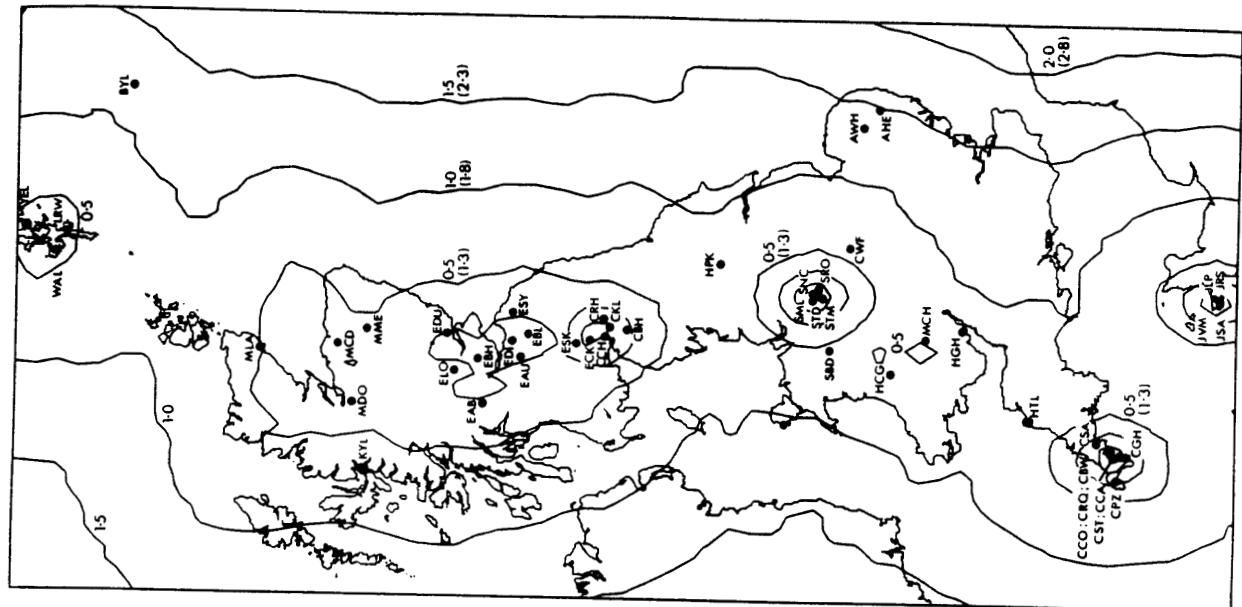

$$V_p/V_s = 1.73$$

Table 6 : Modified Mercalli intensity scale (abbreviated)

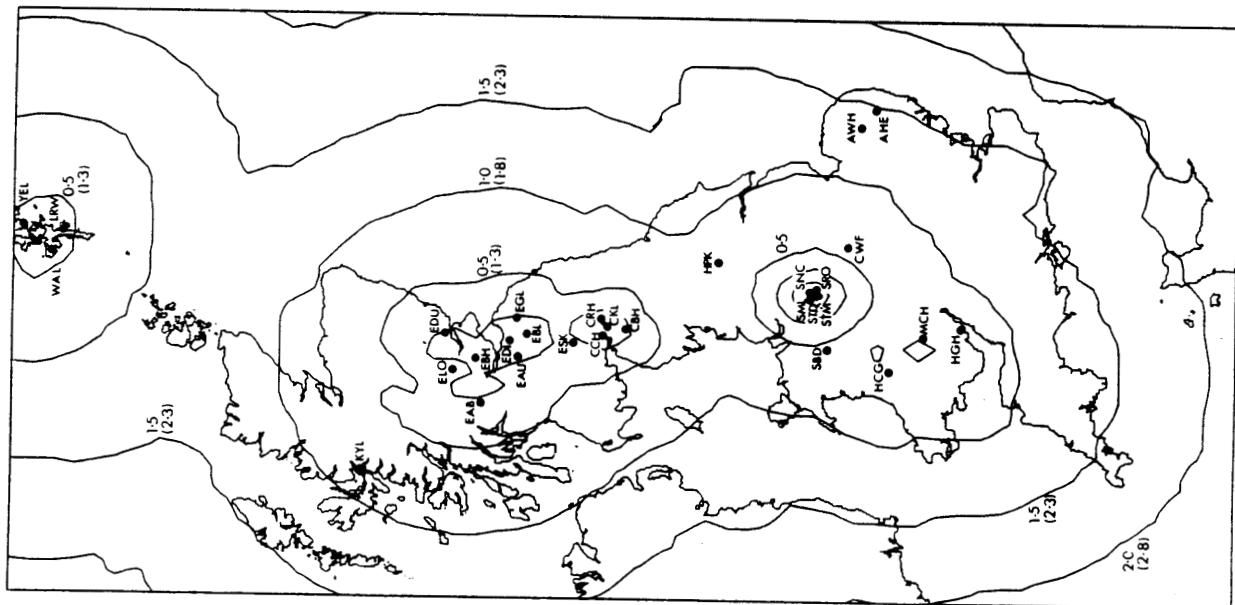

1. Not felt. Marginal and long-period effects of large earthquakes.
2. Felt by persons at rest, on upper floors, or favourably placed.
3. Felt indoors. Hanging objects swing. Vibration like passing of light trucks. Duration estimated. May not be recognized as an earthquake.
4. Hanging objects swing . Vibration like passing of heavy trucks; or sensation of a jolt like a heavy ball striking the walls. Standing motor cars rock. Windows, dishes, doors rattle. Glasses clink. Crockery clashes. In the upper range of IV wooden walls and frame creak.
5. Felt outdoors; direction estimated. Sleepers wakened. Liquids disturbed. some spilled. Small unstable objects displaced or upset. Door swing, close, open. Shutters, pictures move. Pendulum clocks stop, start, change rate.
6. Felt by all. Many frightened and run outdoors. Persons walk unsteadily. Windows, dishes, glassware broken. Knickknacks, books, etc., off shelves. Pictures off walls. Furniture moved or overturned. Weak plaster and masonry cracked. Small bells ring (church, school). Trees, bushes shaken (visibly, or heard to rustle.)
7. Difficult to stand. Noticed by drivers of motor cars. Hanging objects quiver. Furniture broken. Damage to masonry including cracks. Weak chimneys broken at roof line. Fall of plaster, loose bricks, stones, tiles, cornices (also unbraced parapets and architectural ornaments). Waves on ponds; water turbid with mud. Small slides and caving in along sand or gravel banks. Large bells ring. Concrete irrigation ditches damaged.
8. Steering of motor cars affected. Damage to masonry; partial collapse. Fall of stucco and some masonry walls. Twisting, fall of chimneys, factory stacks, monuments, towers, elevated tanks. Frame houses moved on foundations if not bolted down; loose panel walls thrown out. Decayed piling broken off. Branches broken from trees. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes.

Continues to intensity 12 (Damage nearly total).

1981

1980

1979

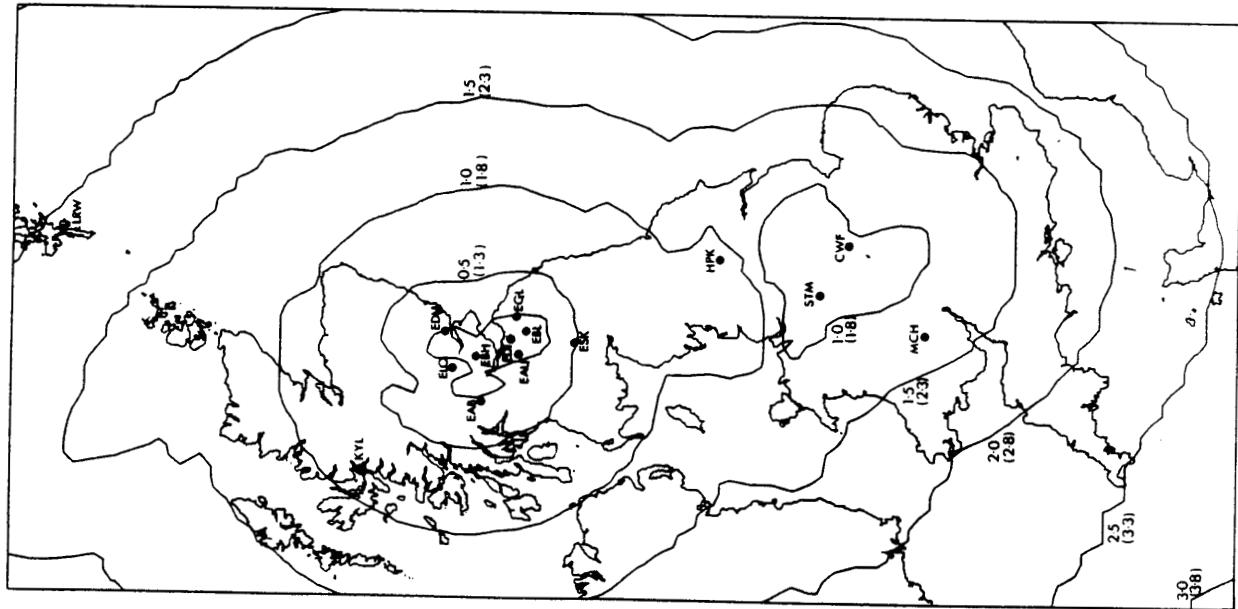

Figure 1 : The seismograph network, 1979, 1980, 1981. The increased detection capabilities for each year are shown by contouring the local magnitudes (ML) of earthquakes below which detection and location is unlikely. The bracketed values of ML apply when there is high background noise.
